Geological Modeling:  
Modeling Long-term Basin Fills

Dr. Irina Overeem  
Community Surface Dynamics Modeling System  
University of Colorado at Boulder

September 2008
Course outline 1

• Lectures by Irina Overeem:
  • Introduction and overview
  • Deterministic and geometric models
  • *Sedimentary process models I*
  • Sedimentary process models II
  • Uncertainty in modeling

• Lecture by Overeem & Teyukhina:
  • Synthetic migrated data
Motivation

• Prediction of source rocks, reservoir, seals and traps requires an understanding of large-scale structural and stratigraphic evolution of the depositional sequences within a basin (i.e. in the exploration phase).

• Stratigraphic evolution determines the large-scale geometry of the depositional sequence, as well as the smaller-scale sedimentary facies and thus the potential reservoir properties.
The interplay of sediment supply, sea level and subsidence

- A/S ratio (Jervey, 1988)

- $A = \text{accommodation} = \text{the space made available for potential sediment accumulation by tectonics and sea level change.}$

- $S = \text{supply} = \text{amount of sediment being delivered to a basin.}$

$A/S > 1: \text{transgression}$

$A/S < 1: \text{regression}$

$A/S = 1: \text{vertical aggradation}$
Milankovitch cycles drive glaciations and consequently sea level fluctuations.
Which process would one need to capture to get first-order estimate of sediment supply?

The sedimentary material is derived from rivers (77%), wind-blown dust (2%), coastal erosion (1%), ice (9%), volcanic ejecta (<1%) and biogenics (8%), aerosols and groundwater (Open University, 1989).
Conceptual longterm basin fill

Numerical Modeling of long-term basin fills
A simple case: sediment supply into a stable basin

- Sediment supply (constant, 4 grainsize classes)
- Process: River channel switching
- Process: Delta Plume deposition

- Model Example: SedFlux-3D
Hypopycnal Plume

• Steady 2D advection-diffusion equation:

\[
\frac{\partial uI}{\partial x} + \frac{\partial vI}{\partial y} + \lambda I = \frac{\partial}{\partial y} \left( K \frac{\partial I}{\partial y} \right) + \frac{\partial}{\partial x} \left( K \frac{\partial I}{\partial x} \right)
\]

where:  
x, y are coordinate directions  
u, v are velocities  
K is turbulent sediment diffusivity  
I is sediment inventory  
\lambda is the first-order removal rate constant
Plume examples

River Mouth Angle = 15 °

River Mouth Angle = 45 °

Stochastic avulsion mechanism

At specific time steps, $t + \Delta t$, the river mouth angle, $A$, changes by an amount drawn from a Gaussian distribution. The rate of switching is controlled by changing the scaling factor, $\mu$ of the Gaussian deviate, $X$. 

$A_{t+\Delta t} = A_t + \Delta \theta$

$\Delta \theta = \mu X$
Avulsions of main delta lobe

The scaling factor $\mu = 0.3$

The scaling factor $\mu = 0.03$

High avulsion frequency results in uniform progradation

Low avulsion frequency results in distinct lobe formation and locally enhanced progradation
The simple case: sediment supply into a stable basin

10 by 10 km basin, 40m water depth, single river, time-continuous supply
Visualize horizon slices, strike and dip sections
SedFlux-3D experiment of a Rift Basin

Example: Lake Malawi, Eastern Rift of the Great Rift Valley

Formed ~35 million years ago due to the rifting and separation of the African and Arabian plates. The lithosphere has stretched significantly and is as a result only 20 km thick as opposed to the normal 100 km.

Lake dimensions: 560 km long, 75 km wide

Bordered by the Livingston Mountains (1500m above lake level), short, steep drainage basins.
Conceptual Model

BORDER FAULT MARGIN DELTA

SedFlux-3D experiment of a Rift Basin
(scenario funded by EXXON-Mobil TX, USA)

• user-specified rapid subsidence
• 5 alluvial fans and their deltas fill the basin
• eustatic sea level change

• duration of experiment = 180,000 yrs
User-defined subsidence

- Stack of Matlab grids $\rightarrow$ subsidence rate $S = f(x,y,t)$ [L/T]
- $S(t_0)$ = subsidence rate at start of simulation
- $S(t_i)$ = subsidence rate at specified time $i$
- Linear interpolation of subsidence rates in intermediate time steps
Rift Basin

rivers carry Qs and Qb

rivers carry only Qs

A couple of other basinfill models

• MAJOR ONES: SEDSIM, DIONYSUS
• QDSSM (Meijer, 2002)
• Integrated tectono-sedimentary model (Clevis, 2003)
SEDSIM: sediment transport based on fluid dynamics (Navier-Stokes equation)

- First version developed at Stanford University, USA (Tetzlaff & Harbaugh)
- Further developed at University of Adelaide and CSIRO, Australia (Dyt & Griffiths)
- SEDSIM example: 16 Ma of basin evolution simulated for exploration purposes (Courtesy of CSIRO, Perth, Australia)
- Input variables:
  - Initial topography
  - Sea-level history
  - Sediment supply
  - Ocean currents and wind field
Coarse sand
Medium sand
Fine sand
Clay
DIONISOS

- Developed at IFP (Granjeon & Joseph, 1999)
- Based on diffusion equation (dynamic-slope model)
- Used in exploration
QDSSM (Meijer, 2002)

- Diffusion-advection
- Delta model
Integrated tectono-sedimentary model (Clevis, 2003)

- Diffusion-advection eqn
- Foreland-basin setting
Summary

- Modeling long-term basin fills is commonly approached by using sequence stratigraphic insights and analysing the A/S ratio.

- Numerical models that simulate subsidence, sea level change and bulk sedimentary processes are a tool to experiment with the different factors controlling the large-scale geometry.
