

Overview of the SiStER code

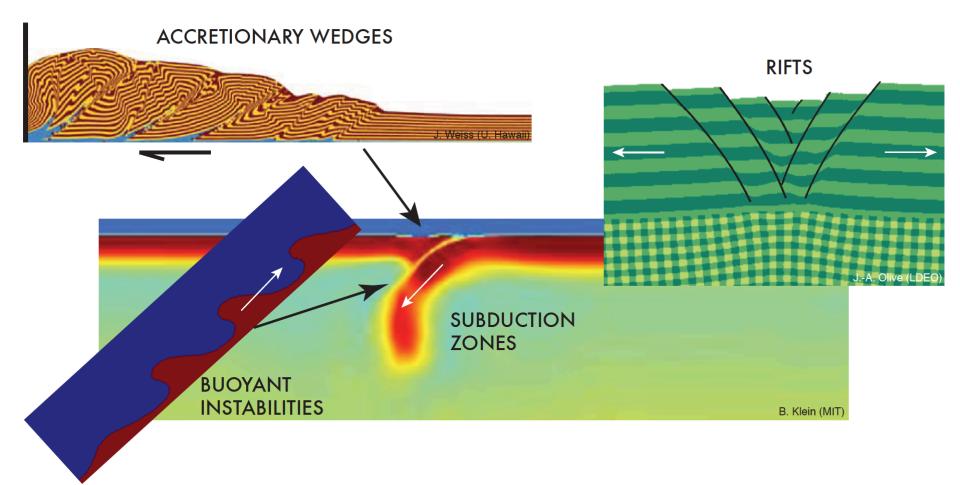

Simple Stokes solver with Exotic Rheologies

Jean-Arthur Olive (LDEO / Columbia University)

In collaboration with E. Mittelstaedt (U. Idaho), B.Z. Klein (MIT), S. Howell (U. Hawaii), M.D. Behn (WHOI), and G. Ito (U. Hawaii)

Objectives & Challenges

Modeling lithosphere and mantle deformation with continuum mechanics: Stokes flow with large strains, strain localization, non-linear rheologies, sharp contrasts in material properties, complex BCs.

Governing equations

Conservation of mass and momentum

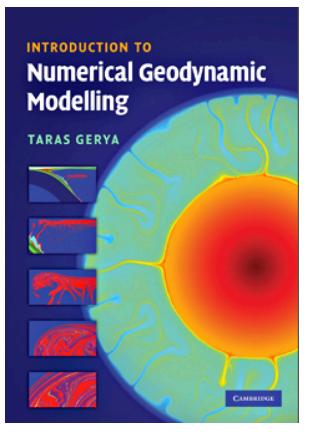

$$\partial_k v_k = 0$$
$$\partial_j \sigma'_{ij} - \partial_i P + \rho g = 0$$

- Non linear viscosity law + elasticity + plasticity
- Conservation of energy

$$\frac{\partial T}{\partial t} + v\nabla T = \nabla \cdot (\kappa \nabla T)$$

Numerical methodology / Citations

• Finite Difference / Particle-in-Cell method. Implementation largely based on *Gerya* [2010].

• Methodology partly described in *Olive et al.* [2016, GJI]

Geophysical Journal International

The role of elasticity in simulating long-term tectonic extension

Jean-Arthur Olive,^{1,*} Mark D. Behn,² Eric Mittelstaedt,³ Garrett Ito⁴ and Benjamin Z. Klein⁵

Finite-difference discretization

Steady-state Stokes flow on Eulerian grid:

Conservative FD scheme on a staggered grid:

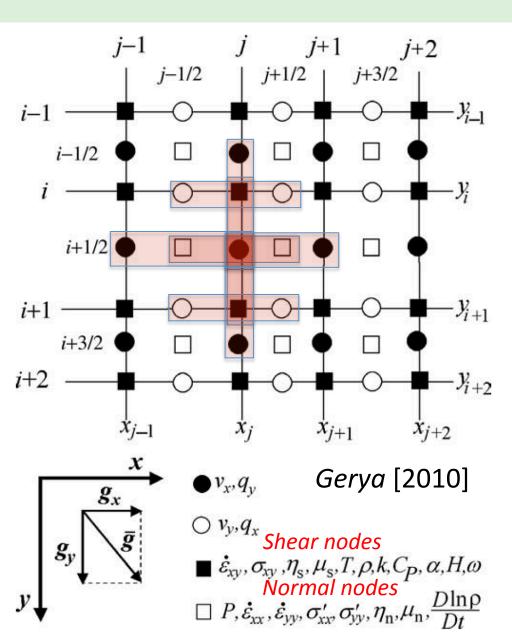

$$\nabla \cdot \left(\eta \left(\nabla v + \nabla v^T \right) \right) - \nabla P + \rho g = RHS$$

 $\nabla \cdot v = 0$

Leads to linear system:

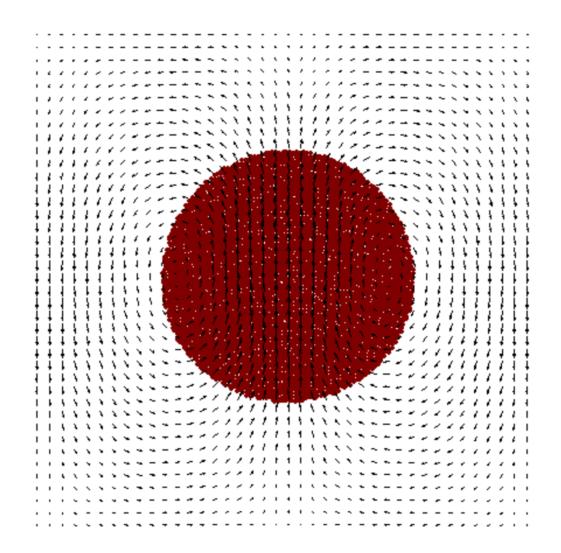

$$JX = \begin{pmatrix} K & G \\ G^T & 0 \end{pmatrix} \begin{pmatrix} v \\ P \end{pmatrix} = \begin{pmatrix} rhs \\ 0 \end{pmatrix}$$

Solved with MATLAB's "backslash" solver.

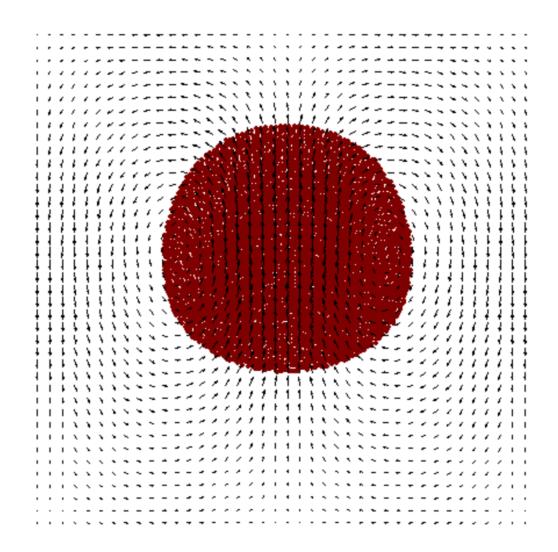

Particles handle material advection

• low density sphere in dense, low viscosity fluid:

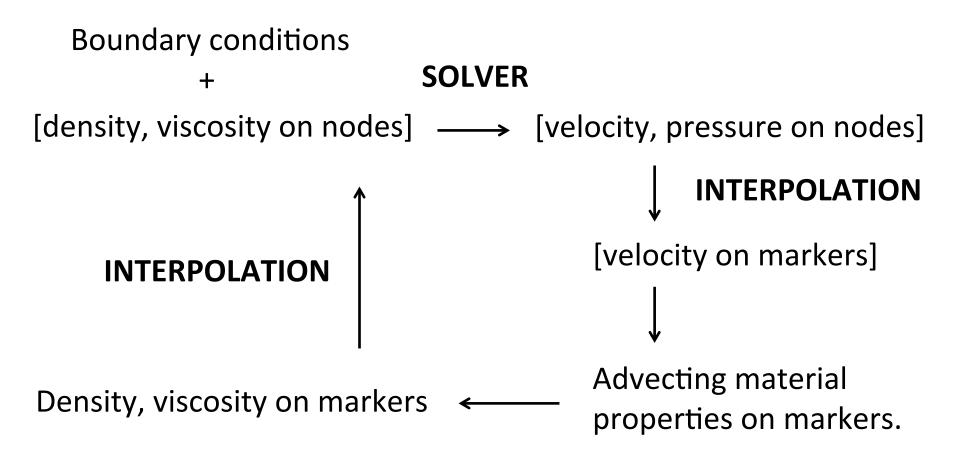

Particles handle material advection

• low density sphere in dense, low viscosity fluid:

Basic code structure

Handling non-linear creep laws

The formulation of viscosity strictly pertaining to non-linear creep laws writes: $\begin{pmatrix} 1 & 1 \end{pmatrix}^{-1}$

$$\eta = \left(\frac{1}{\eta_{DIFF}} + \frac{1}{\eta_{DISC}} + \text{ other terms}\right)$$

This distinguishes the contributions from diffusion and dislocation creep.

Each creep law can be parameterized as: $\eta = A^{-\frac{1}{n}} \dot{\epsilon}_{II}^{\frac{1-n}{n}} e^{\frac{E}{nRT}}$

Picard iterations (SiStER_run_Picard_iterations) consist of:
1/ Solving the flow equations using the latest viscosity map
2/ Calculating the strain rate from the latest solution
3/ Re-evaluating the viscosity from the new strain rate map
Repeat until the solution stops changing (within specified tolerance)

Implementation of visco-elasticity

Maxwell visco-elastic rheology:

$$\dot{\epsilon}_{ij} = \frac{1}{2G} \frac{D\sigma_{ij}}{Dt} + \frac{1}{2\eta} \sigma_{ij}$$

$$= LASTIC \quad VISCOUS$$

$$\longrightarrow FD \text{ approximation}$$

$$\sigma_{ij}^{(t)} = 2 Z \eta \dot{\epsilon}_{ij} + (1-Z) \sigma_{ij}^{(t-\Delta t)}$$
with $Z = \frac{G\Delta t}{\eta + G\Delta t}$

Implementation in a viscous solver: [*Moresi et al.*, 2003]

$$\nabla \cdot (2 Z \eta \dot{\epsilon}_{ij}) - \nabla p + \rho g = - \nabla \cdot ((1-Z)\sigma_{ij}^{(t-\Delta t)})$$

$$au_{Max} = rac{\eta}{G}$$

Maxwell time scale:

For VISCOUS BEHAVIOR set very high G so that: $G\Delta t \gg \eta$, i.e., $\Delta t \gg T_{Max}$ (and $Z \approx 1$)

For **ELASTIC BEHAVIOR** impose high viscosity.

Implementation of plasticity

Plastic (localizing) rheology

Mohr-Coulomb plasticity is implemented by weakening viscosity to cap σ'_{\parallel} at σ_{yield} :

$$\left(\eta = \left(\frac{1}{\eta_{\text{REF}}} + \frac{1}{\eta_{\text{PLAS}}}\right)^{-1}\right) \text{ with } \eta_{\text{PLAS}} = \frac{\sigma_{\text{yield}}}{2\dot{\epsilon}_{\parallel}}$$

Yield stress prescribed through cohesion and friction

 $\sigma_{yield} = \sin \Phi P + C \cos \Phi$

Strain localization is promoted by **dropping cohesion** linearly with accumulated plastic strain ε_p . Full weakening occurs when fault offset reaches $h_c \approx 3 \Delta x \varepsilon_{p \ CRIT}$ Lavier et al. [2000]

Accumulated plastic strain heals on a prescribed time scale

Example case: rifting example

Run SiStER_MAIN, then enter SiStER_Input_File_continental_rift

3

Runs for 100 iterations, will output a file every 10 time steps

Seeding markers to advect material properties:

| 20 | | |
|------|--|--|
| 27 | % LAGRANGIAN MARKERS %%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%% | |
| 28 - | Mquad=6; % number of markers in the smallest quadrant | |
| 29 - | Mquad_crit=3; % minimum number of markers allowed in smallest quadrant (for reseeding) | |
| 30 | | |

The initial marker density is defined such that a quarter of the smallest cell (defined above) has 6 markers, i.e., the smallest cell contains 24 markers. Bigger cells will contain more markers such that the density of markers (number of markers per m²) is constant.

As markers move around, gaps may form in the marker distribution. New markers will be added to fill in the gaps in cells that have quadrants with less than 3 markers.

Setting up the initial geometry of the phases (material types) Here there are 3 phases in total: a sticky air layer, a rock layer and a weak rock inclusion

```

Strain rate is calculated using the current stress and the stress-strain relation, which limits the number of interpolation. The alternative (set value to 0) is to calculate it directly from the velocity solution.

More parameters...

Accumulated plastic strain (in weak yielded zones, i.e., faults) heals exponentially on a time scale specified here, in seconds [*Lavier et al.*, 2000, JGR]. This way, old, abandoned faults where no strain localization is sustained can disappear.

If set to 1, the temperature field will evolve by advection (in the solid flow field) and diffusion.

If set to 0, it will only be advected- the heat equation will not be solved.

Thermal parameters

```
% initial temperature profile, polynomial with depth
136
        % T = a0 + a1*y+a2*y^2+a3*y^3+amp*sin(2*pi*X/lam)
137
        % (make sure it matches the BCs)
138
139 -
        PARAMS.a0=0;
140 -
        PARAMS.a1=0;
141 -
        PARAMS.a2=0;
        PARAMS.a3=1000/(30e3)^3;
142 -
143 -
        PARAMS.amp=0; % amplitude of sinusoidal perturbation
        PARAMS.lam=1; % wavelength of sinusoidal perturbation
144 -
145 -
        PARAMS.ynTreset=1; % if ==1, reset T=T0 where im==1 (sticky layer)
146 -
        PARAMS.T0=0;
        % reference values for the constant diffusivity thermal solver
147
        % (kappa = kref / (rhoref*cpref))
148
        PARAMS.rhoref=MAT(2).rho0;
149 -
150 -
        PARAMS.kref=3;
```

```
151 - PARAMS.cpref=1000;
```

The initial temperature structure follows this functional form:

T = a0 + a1 y + a2 y^2 + a3 y^3 + amp*sin(2*pi x/lam)

See **SiStER_Initialize.m** – Make sure it is not incompatible with the imposed boundary conditions! And do not forget that y=0 is the top of the domain, not of the rock layer (it includes the sticky layer)

Thermal parameters

```
% initial temperature profile, polynomial with depth
136
        % T = a0 + a1*y+a2*y^2+a3*y^3+amp*sin(2*pi*X/lam)
137
        % (make sure it matches the BCs)
138
139 -
        PARAMS.a0=0;
140 -
        PARAMS.a1=0;
141 -
        PARAMS.a2=0;
142 -
        PARAMS.a3=1000/(30e3)^3;
143 -
        PARAMS.amp=0; % amplitude of sinusoidal perturbation
        PARAMS.lam=1; % wavelength of sinusoidal perturbation
144 -
145 -
        PARAMS.ynTreset=1; % if ==1, reset T=T0 where im==1 (sticky layer)
        PARAMS.T0=0;
146 -
        % reference values for the constant diffusivity thermal solver
147
        % (kappa = kref / (rhoref*cpref))
148
        PARAMS.rhoref=MAT(2).rho0;
149 -
150 -
        PARAMS.kref=3;
```

```
151 - PARAMS.cpref=1000;
```

With PARAMS.ynTreset = 1, the temperature field will be automatically set to PARAMS.TO throughout the sticky layer. This is a way to enforce TO at the air-rock interface.

Thermal parameters

```
% initial temperature profile, polynomial with depth
136
        % T = a0 + a1*y+a2*y^2+a3*y^3+amp*sin(2*pi*X/lam)
137
        % (make sure it matches the BCs)
138
139 -
        PARAMS.a0=0;
140 -
        PARAMS.a1=0;
141 -
        PARAMS.a2=0;
        PARAMS.a3=1000/(30e3)^3;
142 -
143 -
        PARAMS.amp=0; % amplitude of sinusoidal perturbation
        PARAMS.lam=1; % wavelength of sinusoidal perturbation
144 -
145 -
        PARAMS.ynTreset=1; % if ==1, reset T=T0 where im==1 (sticky layer)
146 -
        PARAMS.T0=0;
        % reference values for the constant diffusivity thermal solver
147
        % (kappa = kref / (rhoref*cpref))
148
        PARAMS.rhoref=MAT(2).rho0;
149 -
150 -
        PARAMS.kref=3;
        PARAMS.cpref=1000;
151 -
```

The present version of the thermal solver uses a constant diffusivity that can be set here as kref / (rhoref×cpref) This only gets used if PARAMS.Tsolve=1

Picard iterations parameters

| 152 | | <pre>% Picard iterations</pre> |
|-------|---|--|
| 153 - | | PARAMS.Npicard_min=3; % minimum number of Picard iterations per time step |
| 154 - | | PARAMS.Npicard_max=50; % maximum number of Picard iterations per time step |
| 155 - | • | PARAMS.conv_crit1=0.01; |
| 156 - | | PARAMS.conv_crit2=0.03; |
| 157 | | % convergence is assumed if a fraction of the domain smaller |
| 158 | | % than PARAMS.conv_crit2 * domain size has more than relative |
| 159 | | % change of PARAMS.conv_crit1 in strain rate and velocity field |
| 160 | | |

This run will always use at least 3 Picard iterations, but will stop after 50, regardless of the convergence criterion.

Picard iterations parameters

152 % Picard iterations

- 153 PARAMS.Npicard_min=3; % minimum number of Picard iterations per time step
- 154 PARAMS.Npicard_max=50; % maximum number of Picard iterations per time step
- 155 PARAMS.conv_crit1=0.01;
- 156 PARAMS.conv_crit2=0.03;
 - % convergence is assumed if a fraction of the domain smaller
 - % than PARAMS.conv_crit2 * domain size has more than relative
- 159 % change of PARAMS.conv_crit1 in strain rate and velocity field
- 160

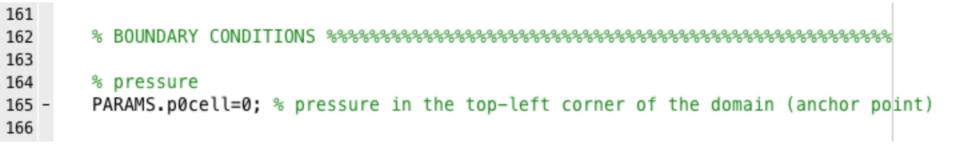

157

158

Convergence is assumed when the strain rate and velocity field change by more than 1% in only 3% of the domain or less. This formulation helps when iterating over the formation of narrow shear bands.

See SiStER_run_Picard_iterations

Boundary conditions (pressure)

Pressure is set to 0 in the top-left corner of the domain. This is done to anchor the solution to a specific pressure and stabilize the inversion.

```
167

175
176 -
        BC.top=[1 0 1.0563e-10];
        BC.bot=[1 0 -1.0563e-10];
177 -
        BC.left=[1 0 -3.1688e-10];
178 -
179 -
        BC.right=[1 0 3.1688e-10];
        PARAMS.BalanceStickyLayer=1; % if set to 1, the code will reset the inflow
180 -
181
        % / outflow BCs to balance the inflow / outflow of sticky layer material,
        % and rock separately, based on the position of the sticky layer / air
182
        % interface
183
184
```

BCs are specified in this BC structure for the top, bottom, left and right edges of the domain. The first entry is 1 for free slip (d v_tangential / d normal = 0), 0 for no-slip (v_tangential = 0)

```
167
                   Boundary conditions (flow)
        % flow
168
169
        % boundary conditions
170
        % entries in BC correspond to
171
        % 1/ rollers? (1=yes, 0=no)
172
        % 2/ type of velocity normal to boundary (0=constant)
173
        % 3/ value of normal velocity
174
175
176 -
        BC.top=[1 0 1.0563e-10];
        BC.bot=[1 0 -1.0563e-10];
177 -
        BC.left=[1 0 -3.1688e-10];
178 -
179 -
        BC.right=[1 0 3.1688e-10];
        PARAMS.BalanceStickyLayer=1; % if set to 1, the code will reset the inflow
180 -
181
        % / outflow BCs to balance the inflow / outflow of sticky layer material,
        % and rock separately, based on the position of the sticky layer / air
182
        % interface
183
184
```

The second entry specifies the type of normal velocity BC – it can only be 0 in the current version, which enforces a constant normal velocity (m/s), specified in the third entry (careful with sign conventions, and make sure inflow matched outflow!)

```
167
                   Boundary conditions (flow)
        % flow
168
169
        % boundary conditions
170
        % entries in BC correspond to
171
        % 1/ rollers? (1=yes, 0=no)
172
        % 2/ type of velocity normal to boundary (0=constant)
173
        % 3/ value of normal velocity
174
175
176 -
        BC.top=[1 0 1.0563e-10];
        BC.bot=[1 0 -1.0563e-10];
177 -
        BC.left=[1 0 -3.1688e-10];
178 -
        BC.right=[1 0 3.1688e-10];
179 -
        PARAMS.BalanceStickyLayer=1; % if set to 1, the code will reset the inflow
180 -
        % / outflow BCs to balance the inflow / outflow of sticky layer material,
181
        % and rock separately, based on the position of the sticky layer / air
182
        % interface
183
184
```

In this example, a velocity of 1 cm/yr is applied towards the right on the right edge, and – 1 cm/yr on the left edge.

The top and bottom velocities are set to balance this outflow.

```
167
                   Boundary conditions (flow)
        % flow
168
169
        % boundary conditions
170
        % entries in BC correspond to
171
        % 1/ rollers? (1=yes, 0=no)
172
        % 2/ type of velocity normal to boundary (0=constant)
173
        % 3/ value of normal velocity
174
175
176 -
        BC.top=[1 0 1.0563e-10];
        BC.bot=[1 0 -1.0563e-10];
177 -
        BC.left=[1 0 -3.1688e-10];
178 -
179 -
        BC.right=[1 0 3.1688e-10];
       PARAMS.BalanceStickyLayer=1; % if set to 1, the code will reset the inflow
180 -
181
        % / outflow BCs to balance the inflow / outflow of sticky layer material,
        % and rock separately, based on the position of the sticky layer / air
182
        % interface
183
184
```

Setting this parameter to 1 will balance the inflow of sticky air and rock separately, based on the position of the air-rock interface at any given time (See **SiStER_flow_solve**)

Boundary conditions (temperature)

```
% thermal
186
187
        % entries in BCtherm correspond to
188
189
        % 1/ type? (1=Dirichlet, 0=Neumann)
        % 2/ value
190
191 -
        BCtherm.top=[1 0];
        BCtherm.bot=[1 1000];
192 -
        BCtherm.left=[2 0];
193 -
        BCtherm.right=[2 0];
194 -
```

Those will be used if PARAMS.Tsolve is set to 1. If the first entry is 1 (Dirichlet), the temperature is set equal to the second entry. If the first entry is 2 (Neumann), the gradient of temperature is set equal to the second entry.

This example has T = 0 on the top, T=1000^oC on the bottom, and no heat flux through the sides.

Visualizing the output

Output files contain (among other things): time (in seconds)

Nodal arrays:

X, Y (coordinates of shear nodes) vx, vy (velocities) and p (pressure)

Marker arrays:

xm, ym (marker coordinates)

im (phase) etam (viscosity) rhom (density) Tm (temperature)
ep (accumulated plastic strain) sxxm, sxym (deviatoric stresses)
epsllm (strain rate)

Topography:

topo_x, topo_y (coordinates of a dense chain of markers tracking the sticky layer – rock interface)

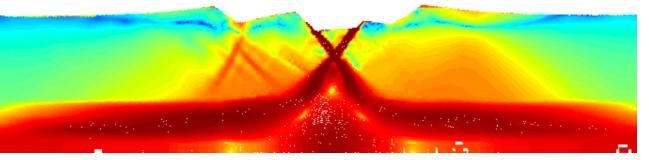

More variables can be output- see I. 96 of SiStER_MAIN

Visualizing the output

To visualize marker arrays (here the strain rate at iteration 100, excluding the sticky air layer):

>> fastscatter(xm(im>1)/1e3,ym(im>1) /1e3,log10(epsllm(im>1)),'markersize',1);

>> axis ij
>> axis equal
>> grid off
>> colorbar
>> caxis([-18 -13])

And the topography:
>> plot(topo_x,topo_y,'k.')
>> set(gca,'YDir','reverse')
